High pH water and high alkalinity in water can be limiting factors in container production of greenhouse floriculture crops. An understanding of both is needed to accurately treat water with a high pH.

Substrate Solution and Water pH Factors

**pH**. A pH reading is a measurement of the hydrogen ion concentration of a solution (how acidic or basic a solution is), and readings range from 0 (most acidic) to 14 (most basic). Availability of micronutrients such as iron, manganese, zinc, copper, and boron and future plant growth can be reduced severely by high substrate and irrigation water pH (Figure 1). High pH water can cause salts to precipitate out of fertilizer stock tanks. High pH water can also reduce the efficacy of pesticides, such as Florel. Therefore, growers should test and know their irrigation water properties.

Although pH 7 is considered “neutral” (not acidic or alkaline), 7 is not the optimum pH for irrigation waters or substrate solutions for nutrient availability and growth in container production due to the substrate components typically used in greenhouse production.

The recommended range of irrigation water pH and substrate solution pH for greenhouse production depends on the crop being grown. The generally accepted pH range is 5.2 to 6.8 for irrigation water and 5.4 to 6.3 for the substrate solution. Acid treatment of your water to about pH 5.8 may be needed prior to use, if the pH and alkalinity are high and result in an out-of-range substrate solution pH (greater than the range given above) when used in on crops.

**Alkalinity**. Alkalinity is a measure of a water’s capacity to neutralize acids. It is the concentration of soluble alcalis in a solution. Dissolved bicarbonates such as calcium bicarbonate (Ca(HCO₃)₂), sodium bicarbonate (NaHCO₃), and magnesium bicarbonate Mg(HCO₃)₂; and carbonates such as calcium carbonate (CaCO₃) are the major chemicals contributing to alkalinity in irrigation water. Dissolved hydroxides are but a minor contributor in most cases. Ammonia, borates, organic bases, phosphates, and silicates can also be minor contributors to alkalinity.

**Total carbonates**. Since bicarbonates and carbonates are the major components of water alkalinity, most laboratories assume that Total Carbonates (TC = carbonates + bicarbonates) equals alkalinity. In most cases, this is a safe assumption. For most waters in the Southeast, bicarbonates account for more than 90% of all alkalinity present.

The term “alkalinity” should not be confused with the term “alkaline,” which describes situations where pH levels exceed 7.0. Laboratory test results will express alkalinity as milligrams per liter (or parts per million) of calcium carbonate (mg/L or ppm CaCO₃) or as milliequivalents per liter of calcium carbonate (meq/L CaCO₃). You can convert between these two units using the following values: 1.0 meq/L CaCO₃ = 50.04 mg/L CaCO₃. The term “total carbonates” (TC) may also be used by some testing laboratories to refer to alkalinity.

![Figure 1. Influence of pH level on the availability of essential nutrients in a soilless substrate containing sphagnum peat moss, composted pine bark, vermiculite, and sand. The pH range recommended for most greenhouse crops is indicated by slashed lines.](image-url)
of a solution. Some laboratories assume that all alkalinity is derived solely from bicarbonates (HCO$_3^-$) and will report alkalinity as bicarbonates using ppm (mg/L) or meq/L. To convert between these two units, use the following values: 1 meq/L HCO$_3^-$ = 61 mg/L HCO$_3^-$.

Alkalinity is related to pH because alkalinity establishes the buffering capacity of a water. Alkalinity affects how much acid is required to change the pH. The following example may help explain the importance of alkalinity when trying to acidify water (Figure 2): Grower A has a water with a pH of 9.3 and an alkalinity of 71 mg/L CaCO$_3$ (TC = 1.42 meq/L). To reduce the pH of this water to 5.8, it takes 15.8 fl oz. of 35% (w : w) sulfuric acid per 1,000 gallons of water. In contrast, Grower B has a water with a pH of 8.3 and an alkalinity of 310 mg/L CaCO$_3$ (TC = 6.20 meq/L). To reduce this water to a pH of 5.8, it takes 68.6 fl oz. of 35% sulfuric acid per 1,000 gallons of water. Despite the fact that Grower B’s water is a full pH unit lower than Grower A’s, it takes more than four times more acid to lower the pH to 5.8. Both alkalinity and pH are important to consider when adjusting the pH of a water.

Alkalinity can be a major problem in the Southeast, especially in the coastal plains. Levels of 2 meq/L and lower are safe for most crops. However, plug seedlings are more sensitive to alkalinity because the small volume of substrate provides little buffering against a rise in pH. Problems can occur in plug production if using water with more than 1.5 meq/L. If the alkalinity of your irrigation water is above 2.0 meq/L (or above 1.5 meq/L for a plug producer), you should consider injecting an acid to neutralize the bicarbonates (alkalinity) present, thus preventing an undesirable rise of substrate pH over time.

**In-House Analysis of Water pH and Alkalinity**

**pH.** Many relatively inexpensive ($30 to $250) pH meters are available that are accurate enough for greenhouse use. When selecting a pH meter, look for an accuracy of ±0.1 pH unit and a range of 1 to 14. You should also be able to calibrate the meter (meter should have some type of calibration adjustment such as a set screw). Make sure to order standard pH solutions (usually pH 4.0 and pH 7.0) in order to calibrate

---

**Figure 2. Titrations of two different waters with sulfuric acid. Notice that although the beginning pH of Grower A water is a full unit higher than Grower B water, it takes more than 4 times the acid to drop Grower B water to pH 5.8, due to the greater alkalinity in Grower B water.**
Avoid skin and eye exposure when handling any acid. Acid-resistant eye wear, gloves, and apron should be worn. Acids are corrosive and can damage clothing that is not immediately rinsed.

When mixing acid stock solutions, always add acid to a larger volume of water to create the stock. Never add water to concentrated acid.

Cost. In general, sulfuric and nitric are less expensive than phosphoric and citric (Table 1). Citric acid is somewhat cost prohibitive for uses other than neutralization of water used in pesticide sprays and in fertilizer stock solutions. Note the prices used in these calculations. Acid prices do vary with supplier and quantity. You may need to recalculate acidification costs using your acid costs.

Nutrients from acids. With the exception of citric acid, the acids used for water acidification also supply a plant nutrient in conjunction with supplying H⁺. The nutrient supplied can be beneficial to plant growth (if not supplied in excess), but it can also react with fertilizer salts in concentrated solution or in spray solutions.

Growers who acidify their water should adjust their fertilization program for the nutrient supplied by the acid used (Table 1). For example, if using phosphoric acid, make sure to reduce your phosphorus feed accordingly to account for the P supplied from the acid. When attempting to acidify waters very high in alkalinity, phosphoric acid may not be feasible. For example, if your water supply contains 6.0 meq/L of alkalinity and you used phosphoric acid to neutralize the alkalinity, over 126 ppm P (280 ppm P₂O₅) are supplied at each irrigation, an extremely high level of phosphorus. A maximum of 55 ppm P (125 ppm P₂O₅) is recommended. Use another acid if more than this amount of P is being injected from phosphoric acid. If using nitric acid, account for the additional N supplied from the acid. Using 67% nitric acid to acidify water containing 6.0 meq/L of alkalinity would supply 67 ppm N at each irrigation, a significant quantity of nitrogen. Sulfuric acid treatment for 6.0 meq of alkalinity would supply 75 ppm S, more than sufficient sulfur for plant production (20 to 30 ppm S is suggested for most floriculture crops).

Acid recommendations. Citric acid is ideal as an acidifier for nutrient stock solutions and pesticide solutions, as it is much less likely to react with fertilizer salts or pesticides than the other three acids. Use citric acid for acidifying water used to make concentrated fertilizer stocks and pesticide solutions. However, the cost of citric acid makes it less desirable as an acidifier for large volumes of water used for irrigation and fertilization.

For acidification of irrigation water, we recommend sulfuric acid over nitric acid due to its relative safety. Sulfuric is recommended over phosphoric acid for very alkaline water due to the higher cost of phosphoric acid and the possibility of over application of P. The sulfuric acid recommended is a battery electrolyte product named Qual® and can be purchased from most auto supply stores for about $10 per 5 gallons.
To accurately predict the amount of acid required to acidify to a given pH, both the pH and alkalinity of the irrigation water must be known. Table 1 outlines starting amounts of acid to inject to drop the pH to approximately 5.8. However, this table is only taking alkalinity into account (and does not account for the starting pH of a water sample), and fine tuning of the amount of acid added will be necessary. When acidifying water, an end point of 5.8 is adequate to control substrate solution pH rise due to alkalinity in the irrigation water.

</tbody>
</table>

*Add this amount for each meq/L of alkalinity present. For example, if your water report indicates an alkalinity of 3 meq/L and you choose to use sulfuric acid, you would add 33 fl oz of 35% sulfuric acid per 1000 gallons of water (11 fl oz/meq/L x 3 meq/L = 33 fl oz). Calculations based on the following dissociation values: 2.07 meq H+ per 3 meq H₂C₆H₅O₇, 1 meq H+ per 1 meq HNO₃, 1.02 meq H+ per 3 meq H₃PO₄, and 1 meq H+ per 1 meq H₂SO₄.

**Acid cost to neutralize 1 meq/L alkalinity per 1000 gallons of water. Based on the following costs: $1.04/lb of 99.5% citric acid; $8.45/gal of 50% citric acid; $5.00/gal of 67% nitric acid; $7.00/gal of 75% phosphoric acid; $1.90/gal of 35% sulfuric acid.

***Use caution with ALL acids. Wear eye protection, acid-resistant gloves, and an acid-resistant apron when handling any acid.

Acid injection equipment. The injector used to add the acid into your water should be approved for acid injection by the manufacturer. Consult the manufacturer to select an injector for acid injection.

Do not mix acid stock solutions with fertilizer stock solutions, as fertilizer salts could precipitate out of solution with certain acid/fertilizer combinations. Use separate injectors for each solution.

Acidic water will corrode galvanized piping and fittings over time. Be sure to check the integrity of greenhouse plumbing periodically.
